doc for detail The following 16 files are pseudo-files used by this generated `eeps.5EPS2D.3d` (EPS output),\ `eeps.5EPS2D.3D` (PDF output),\ `eeps.5EPS2D.eps` (EPS input) and\ `eeps.5EPS2D.pdf` (PDF input) The pseudo-files have the same names as the eps/pdf files produced. This is a `Latex` package file, using the `TeX` extensions to `.sty` and `.cls` files and a simple `.tex` input to produce an EPS file (to provide an eps input). If you use a commercial EPS-producing program (such as `Quadros`), you can usually specify the extension to be `.5EPS2D` and then the EPS output file will be created with this extension. The `.sty` file is an `EPS` version of the `.tex` input. You can use this package with the standard `.sty` file, or just type the following: \usepackage{EES.Engineering.Equation.Solver.Commercial.Ver6} The EPS version of the file will be produced. The EPS file name can be changed by replacing `EPS.Engineering.Equation.Solver.Commercial.Ver6p883.3D` in the code by

the desired filename. This filename is always the same as the `.5EPS2D` extension of the `.tex` file, but it can be different from the `.eps` filename. To make the `.5EPS2D` files seeable, you need to give the path to ``epeps.sty`` and the ``cls`` file. Using the input you can choose the values for all the parameters of the EPS output, in a similar way as you choose the values of the parameters in the `.tex` input. A typical calculation shows the coefficients of a second order equation in the following way: `\begin{document}`

`\begin{equation*} f3e1b3768c`
