A: This is now fixed - thanks for the report! Post navigation Energy Saving Car Batteries The majority of cars now have energy-saving electric batteries as the primary or secondary power source. While the technology and design of energy-saving car batteries have evolved, energy saving car batteries are commonly used today in four-cylinder vehicles. The technology that enables the electric battery to give off heat to its surroundings when in use is referred to as regenerative braking. When a driver presses on the gas, the regenerative braking system is activated. This process forces energy back to the battery. It then causes the battery to produce power, which is released into the vehicle as electricity. Car batteries have been a major contributor to carbon emissions for years. Yet, because of the increased use of electric vehicles in the United States, car batteries have been an important factor in the reduction of carbon emissions. Reducing Carbon Emissions in the Air Carbondioxide (CO2), a major contributor to global warming, is emitted into the air by the use of gasoline, diesel and other fuels in motor vehicles. Carbondioxide emissions are reduced when the battery is in its most efficient state, meaning when it is close to its optimum capacity. Additionally, when a driver releases the accelerator pedal, the energy output is stored. This energy is then used in the regenerative braking process. Electric Battery Technology There are a number of types of batteries used in car batteries. Primary batteries consist of one rechargeable battery. The battery is referred to as primary because it is used first to power the car. When the battery is depleted, it can be charged again to produce more energy. This is similar
