ScFv antibodies are made by linking the heavy and light chains of the immunoglobulin heavy and light chain genes to make a single chain polypeptide. One preferred way to make ScFv antibodies is to use the expression vector pComb3X1, containing ScFv antibody sequences which was first disclosed in U.S. Pat. No. 4,946,778. pComb3X1 is a vector having a multiple cloning site (MCS) and which also contains the inducible alcohol dehydrogenase promoter (AdhP). pComb3X1 also contains a polylinker, which is a multiple cloning site. Each cloning site allows the insertion of different DNA sequences. The polylinker contains the ClaI, SalI, BglII, EcoRI, and SmaI sites, which are usually found in the sequences encoding antibody light chain variable region (VL) and heavy chain variable region (VH) genes and other antigen-specific sequence. In order to be able to produce desired antibodies, one typically cloned VH and VL regions of an antibody gene into one or both of the pComb3X1 and into a second expression vector which has the appropriate promoter to direct expression of VH and VL, either in the same cell or in different cells. Expression is usually achieved by transfecting the two expression vectors into a host cell. A host cell is transformed or transfected with two or more expression vectors, the individual vectors each containing one of the appropriate antibody gene sequences. Transcription of the antibody genes in these expression vectors can be regulated using the AdhP promoter. As a further refinement, when using two expression vectors, each containing one of the antibody genes, the two expression vectors can be selected such that the two genes are regulated by different promoters. This may be achieved by placing one promoter in each vector or by placing the promoters in a separate vector. This can be achieved, for example, by using the AdhP promoter for the first vector and the ltetO
